## Abstract

Large language models (LLMs) and vision-augmented LLMs (VLMs) have significantly advanced medical informatics, diagnostics, and decision support. However, these models exhibit systematic biases, particularly age bias, compromising their reliability and equity. This is evident in their poorer performance on pediatric-focused text and visual question-answering tasks. This bias reflects a broader imbalance in medical research, where pediatric studies receive less funding and representation despite the significant disease burden in children. To address these issues, a new comprehensive multi-modal pediatric question-answering benchmark, PediatricsMQA, has been introduced. It consists of 3,417 text-based multiple-choice questions (MCQs) covering 131 pediatric topics across seven developmental stages (prenatal to adolescent) and 2,067 vision-based MCQs using 634 pediatric images from 67 imaging modalities and 256 anatomical regions. The dataset was developed using a hybrid manual-automatic pipeline, incorporating peer-reviewed pediatric literature, validated question banks, existing benchmarks, and existing QA resources. Evaluating state-of-the-art open models, we find dramatic performance drops in younger cohorts, highlighting the need for age-aware methods to ensure equitable AI support in pediatric care.

## 1 Introduction

Artificial intelligence (AI) has seen a rapid and widespread increase in its application to medical domains [8, 7, 1, 15, 6]. These applications range from simple information management [1], to detection and diagnostics [15, 4] by using various techniques. Large language models (LLMs) and vision large language models (VLMs) are such techniques [49]. LLMs and VLMs have been used extensively in specialised and generalist capacities in various medical applications [49, 36, 23]. However, multiple works found that these models suffer from different pitfalls (e.g. Hallucinations [2], bias [6], uncertainty [43], privacy issues [41], etc) that reduce their reliability. One of the most prominent issues is age bias. Age bias has been shown to exist at various levels of LLMs. In fact, [6] showed a significant age bias in known medical text question answering (TQA) benchmarks, which contain information more relevant to older than younger people. In addition, [43] showed that various VLMs perform in older age groups better than in younger age groups in the task of vision question answering (VQA). These works prove systemic neglect exists in LLM medical applications for younger people.

This phenomenon is not exclusively present in LLMs, but it is rather an inherent part of medical research. In fact, various works [29, 24] demonstrated that pediatrics is relatively understudied and under-explored. [10] found that despite children accounting for nearly 60% of the disease burden in certain conditions, only about 12% of clinical drug trials focus on pediatric patients. [29] Found that studies involving adults are significantly more likely than child studies to be randomized controlled trials, systematic reviews, or studies of therapies. [32] showed that pediatric research funding

has historically been lower compared to adult research. These observed attitudes toward pediatric care inadvertently affect the quantity and quality of pediatric literature, which can influence the performance of LLMs in pediatrics. This neglect of child medicine can have significant ramifications on the adaptation of LLM-based applications in the case of pediatric care.

In a step towards a fairer, more robust evaluation of LLMs and VLMs in pediatrics, this work proposes PediatricsMQA. PediatricsMQA contains TQA and VQA multi-choice questions (MCQs) and their corresponding right answers. PediatricsMQA is constructed through a hybrid manual and automatic process from various sources (e.g. pediatrics journals articles, MCQ banks, pediatrics books, pediatrics QA pairs in previous benchmarks etc). PediatricsMQA is a rich representation of the field of pediatrics composed of TQA pairs 3417 about 131 pediatrics-related topics at 7 different child development stages (i.e. Prenate: -9 months to 0 weeks, Neonate: 0 weeks to 4 weeks, Infant: 1 month to 1 year, Toddler: 1–3 years, Preschool: 3–5 years, School-Age: 6–12 years, Adolescent: 13–18 years). In addition, PediatricsMQA contains 2067 VQA pairs on 634 images containing 67 modalities and 256 anatomical regions for male and female children at 7 different development stages. Extensive experiments on various publicly accessible LLMs show that PediatricsMQA represents a challenging benchmark. The dataset<sup>1</sup> and code<sup>2</sup> are made available. Various findings were established as part of this work: **PediatricsMQA Difficulty:** The PediatricsMQA dataset is more challenging than other medical QA benchmarks, leading to lower model accuracies and revealing the complexity of pediatric reasoning. **Model Size Matters:** Newer and larger models (e.g., Llama-4-Maverick, Gemini-2.0-Flash) outperform smaller or older ones (e.g., MedAlpaca-7B), showing that model scale and sophistication are critical for pediatric QA. **Age Group Variability:** Model performance varies significantly across pediatric age groups. VQA models perform better on Neonates and Infants but struggle with Adolescents and Preschoolers. **Topic Sensitivity in TQA:** Models struggle with topics like “Lipid Disorders” and “Pharmacology,” but perform better on areas like “Developmental Psychology,” highlighting uneven reasoning across pediatric topics. **Anatomical Region Challenges in VQA:** Models excel with internal/frequently imaged regions (e.g., blood cells) but underperform on ambiguous or peripheral regions (e.g., gums, genitalia). **Modality Impact in VQA:** Structured modalities (e.g., optical images, IHC) yield higher accuracy, while complex ones (e.g., cytopathology, natural images) pose greater challenges. **Shared Limitations Across Models:** Regardless of architecture, all models exhibit similar weaknesses with certain modalities and topics, pointing to fundamental challenges in pediatric medical QA.

## 2 Previous Literature

### 2.1 LLMs and VLMs

The recent wave of advancement in natural language processing focused on instruction following LLMs [30, 33, 38]. These models showed remarkable performance and generality across a plethora of tasks (e.g. classification, summarisation, question answering, etc) and domains (e.g. finance, medicine, etc). Various LLMs were supplemented by a vision module to create VLMs. VLMs align vision and language to create an LLM with visual perception able to achieve various vision-related tasks (e.g. image captioning, VQA etc) in various domains (e.g. finance, medicine, law, etc). Since the inception of this new paradigm, various works have explored the feasibility and applicability of LLMs and VLMs to medical applications. Works such as [44, 40, 42] fine-tuned existing open-source LLMs on medical instruction data. [13] pretrained and then finetuned an LLM on a large medical corpus. In addition, various works employed VLMs to solve medical vision tasks [26, 12, 48, 19, 16, 11, 3]. Although these models demonstrated remarkable performance on different tasks, they were shown to suffer from various pitfalls. One of these pitfalls is age bias. In fact, [6] showed that TQA benchmark datasets contain information that is significantly more relevant to older people than younger people. [43] showed that VLMS demonstrated a significant age bias and performed relatively well on older people than younger people. This neglect of pediatric care motivated this work, which proposes a novel medical benchmark for pediatrics, containing TQA and VQA pairs.

<sup>2</sup><https://github.com/BahajAdil/PediatricsMQA>

## 2.2 Medical Benchmarks

Benchmark datasets are an important part of a model’s life cycle, without which models cannot be evaluated on an equal footing. Various medical benchmarks have been proposed [19] for various tasks (e.g. TQA [31, 20, 21], VQA [19, 48], summarisation [14], report generation [46, 37]). QA benchmarks are particularly informative in medical applications because they quantify the factuality and exactitude of medical knowledge in LLMs and VLMs. However, works like [6] demonstrated the significant imbalance that exists between child and adult questions in various frequently used medical QA benchmarks. This limits the trustworthiness of existing LLMs and VLMs in pediatrics. This work tries to remedy this gap by proposing a new benchmark dataset for pediatric medicine. To our knowledge, there are only two datasets for pediatrics QA PediatricsQA [6] and PediaBench [47]. PediatricsMQA represents various advantages relative to these benchmarks. First, it extends TQA pairs of PediatricsQA and adds more TQA pairs in addition to containing highly curated VQA pairs. On the other hand, PediaBench only contains pediatrics TQA pairs in Chinese, which limits its adoption as a benchmark since most LLMs are trained on an English corpus.

## 3 PediatricsMQA Dataset

PediatricsMQA contains: a) TQA and b) VQA pairs. These two types of questions in PediatricsMQA differ in their modality and the way they are constructed. Although there are various types of QA pairs in literature (e.g. binary QA pairs, MCQs pairs, open-ended QA pairs), PediatricsMQA contains only MCQs since they are harder than binary QA pairs, as they contain multiple options presenting a more challenging benchmark. In addition, MCQs are a more exact tool to assess the knowledge of LLMs than open-ended QA pairs. In what follows, we detail their construction process.

### 3.1 Construction process

#### 3.1.1 TQA Data Construction

This part of PediatricsMQA is built upon and extends PediatricsQA [6]. PediatricsQA contains 831 TQA pairs, which were extended in PediatricsMQA to 3401 TQA pairs. To construct the new TQA pairs, many medical sources were used (e.g. Books, question banks, medical exams, etc). We used various books that either contain QA pairs [5] or that contain pediatrics medical knowledge [9]. TQA pairs are either made or extracted manually from books containing TQA pairs and pediatrics medical books, respectively. These questions belong to a diverse set of categories and child development stages, presenting various physical and psychological phenomena in pediatrics (Figures 1 and 2). To avoid any unintentional copyright issues, we used an LLM (Gemini-2.0-Flash) to paraphrase the questions and the options (see appendix B), in addition to changing the order of the options and the index of the right answer. Another round of manual filtering is conducted to remove any questions with obvious answers or questions that require contextual information to be answered. Although the vast majority of questions are about children, some questions about women’s pregnancy are left due to their importance for pre-nate children’s health.

#### 3.1.2 VQA Data Construction

VQA pairs are extracted from two kinds of sources: a) based on previous benchmarks with demographic information (i.e. age), b) based on images and text from pediatrics journals.

**Based on existing benchmarks** Two benchmark datasets containing children’s images are used: HAM10000 [39] and FairVLMed [28]. In both datasets, a subset of imaging and related metadata for people whose age is below 18 is taken. Since HAM10000 contains metadata about the localisation and diagnosis of the lesions present in the image, this metadata is used to create multiple VQA pairs through a template for the questions and options (Figures 9 and 10). The FairVLMed dataset medical notes that describe the image and the case, which are transformed to multi-choice questions using Gemini-2.0-Flash, by supplementing the LLM with the medical notes and the image and prompting it to produce 5 questions with their corresponding options and answers (Figure 8). These MCQs are later filtered manually to leave only questions that can be answered visually and where the information is contained in the given clinical notes.

PediatricsMQA					
TQA		VQA			
#QA pairs	# Categories	#QA pairs	#Images	# Anatomical regions	# Modalities
3417	131	2067	634	256	67

Table 1: Summary Statistics. PediatricsMQA is composed of two main subsets of text QA pairs and vision QA pairs.

**Based on pediatrics journals** In this case, VQA pairs are extracted through the following steps: a) scraping, 2) generation, 3) curation. First, a set of images and their corresponding captions and passages from different scientific articles are obtained by scraping the journal of "Case Reports in Pediatrics" [22]. This journal contains a plethora of articles about various cases of children with a diverse set of physical and psychological phenomena. Second, each image and its corresponding caption and passage are fed to a VLM (Gemini-2.0-Flash in our case) with a prompt instructing it to generate five relevant MCQs with their corresponding answer from the image in the context of the caption and the passage. Third, we noticed that different questions and answers were either out of context or were visually unanswerable (i.e. they require access to the caption and the passage to be answered). Consequently, manual curation was used to filter out low-quality QA pairs. Human labellers are tasked with adding two fields to each VQA pair: a) **question source** and b) **answer source**. The question source indicates if the question explicitly states that it requires access to the caption or passage, e.g. "based on the caption, ...". The answer source field indicates whether the answer is present in the caption and passages or is based on the internal knowledge of the LLM. The kept VQA pairs are those where the question is visual and the answer is contained in the context (i.e. passage + caption). An additional manual labeling step is conducted to extract the age and gender of each image from the article. All adult images are filtered out except those where a child is included (e.g. pregnant woman's CT scan or ultrasound).

### 3.2 Variations in the Data

The dataset contains various dimensions of variation. The following lists a few:

- **QA Tasks:** PediatricsMQA contains two subsets of TQA and VQA pairs, respectively. Each question is paired with multiple options (from 4 to 6 options), one of which is the right answer.
- **Categories and topics:** PediatricsMQA TQA pairs dataset contains a plethora of categories that deal with various topics ranging from basic psychological QA pairs to more advanced surgical QA pairs (Figure 1).
- **Modalities:** PediatricsMQA VQA pairs belong to a diverse set of categories ranging from simple clinical imaging to more specialised imaging techniques like MRI and ultrasound (Table 1).
- **Demographics:** The dataset is also diverse across various demographic dimensions, including age and gender (Figures 3, 2). In addition, VQA pairs of PediatricsMQA are about a range of internal and external anatomical regions (Table 1).
- **Medical Tasks:** PediatricsMQA QA pairs pertain to a range of medical tasks including: general knowledge, disease diagnosis, disease detection, anomaly detection etc

Table 1 summarizes key stastics of the dataset. Appendix A shows a few examples from the dataset.

## 4 Results

### 4.1 Benchmarks

Various flagship medical benchmarks are used to compare their performance to that of PediatricsMQA in TQA and VQA. For TQA, we report the performance of PediatricsQA [6], PubMedQA [21], MedQA [20], and MedMCQA [31]. For VQA, we report the performance of VQA-RAD [25], SLAKE [27] and PathVQA [18].

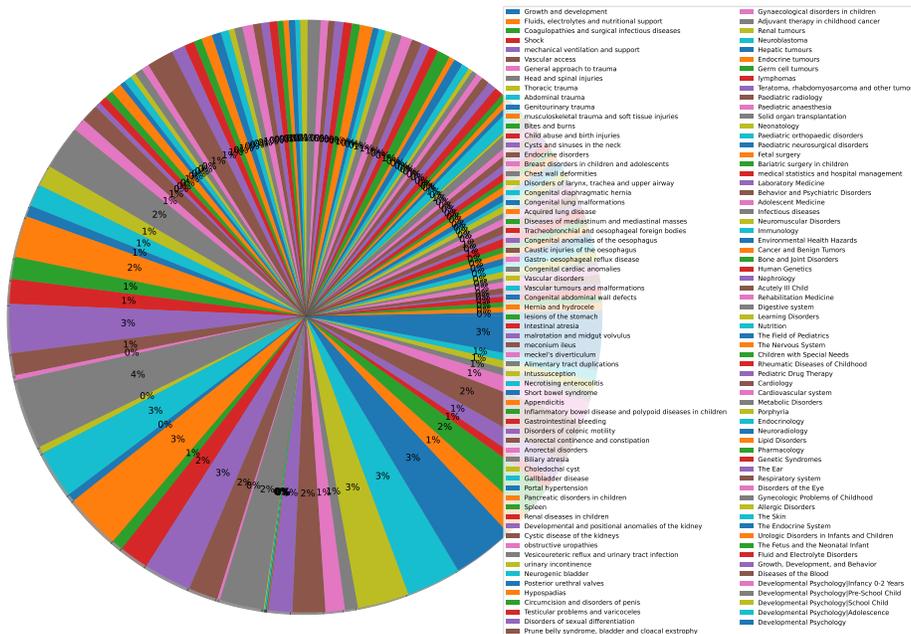

Figure 1: The different categories in TQA pairs in PediatricsMQA.

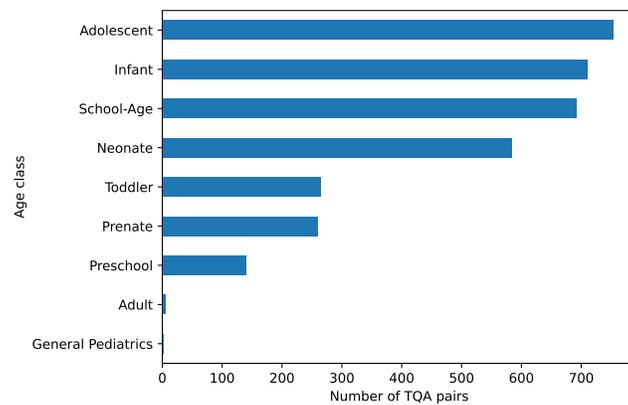

Figure 2: Distribution of different young people age groups in the TQA subset of PediatricsMQA. The following are the age group and their corresponding age range: Prenate: -9 months to 0 weeks, Neonate: 0 weeks to 4 weeks, Infant: 1 month to 1 year, Toddler: 1–3 years, Preschool: 3–5 years, School-Age: 6–12 years, Adolescent: 13–18 years

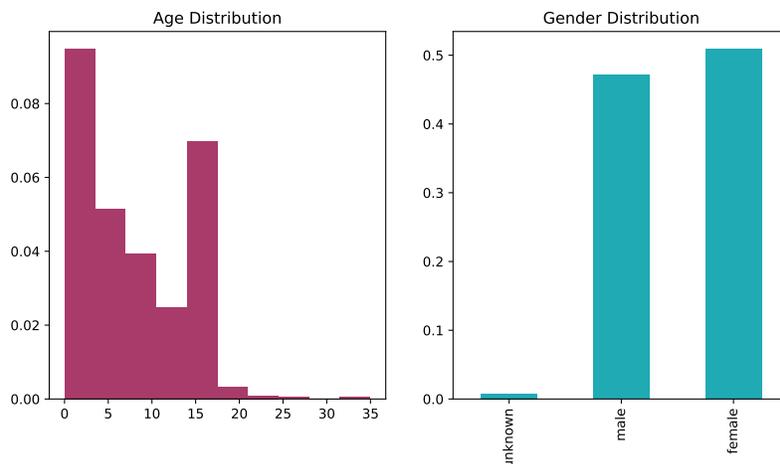

Figure 3: The distribution of age and gender in the TQA part of PediatricsMQA. The existence of some adult images and unknown genders is due to images of prenat babies which are still in gestation.

## 4.2 Baselines

Different open and closed weight models are evaluated on TQA and VQA tasks for PediatricsMQA and other medical benchmarks. For TQA, we report the performance of MedAlpaca, Llama-Medx<sup>3</sup>, Gemini-1.5-Flash[45, 34], Gemini-2.0-Flash[45, 34], LLama-3.1 (8B) [17], Llama-4-scout (17B) [35], Llama-4-Maverick (17B) [35]. For VQA, we report the performance of LLaVa-Med-7B [26], HuatuoGPT-Vision-7B [11], Gemini-1.5-Flash[45, 34], and Gemini-2.0-Flash[45, 34].

## 4.3 Experimental setting

The models are evaluated using the different benchmarks in addition to PediatricsMQA. We report the accuracy of each model in answering the different questions. For the VQA benchmarks, we only report the results of the closed setting, since it is a more comparable setting than the open setting. We use the default splits provided in the original papers corresponding to each dataset. All the datasets are evaluated using the test split, except MedMCQA, where we used the validation split since the test split doesn't have any ground truth labels. The experiments were conducted using various mediums. Some experiments were conducted in a local machine equipped with an RTX 3090 GPU. These experiments are in the following models: MedAlpaca, Llama-Medx, LLaVa-Med (7B), HuatuoGPT-Vision (7B). Other experiments were conducted using API calls for the Gemini models using Google AI Studio and Groq for the following models: LLama-3.1 (8B), Llama-4-scout (17B) and Llama-4-Maverick (17B).

## 4.4 Performance

Tables 2 and 3 compare the performance of various language and vision-language models, respectively. In the TQA results (Table 2), the PediatricsMQA dataset proves to be a more challenging benchmark than established datasets like PubMedQA or MedQA, with overall lower scores across models. However, high-performing models such as Llama-4-Maverick and Gemini-2.0-Flash demonstrate strong capabilities, achieving top scores across nearly all datasets, including PediatricsMQA. In contrast, earlier or smaller-scale models like MedAlpaca1 and LLama-3.1 show significantly lower performance, especially on pediatric data, highlighting the added complexity of this domain. Similarly, in the VQA setting (Table 7), PediatricsMQA again emerges as a more demanding testbed, particularly for models such as LLaVa-Med, which shows its weakest performance on this dataset. Nevertheless, Gemini-2.0-Flash and HuatuoGPT-Vision achieve competitive results, demonstrating their strength in handling multimodal medical content. Overall, the results underscore the relevance and difficulty of

<sup>3</sup>[https://huggingface.co/skumar9/Llama-medx\\_v3.2](https://huggingface.co/skumar9/Llama-medx_v3.2)

the PediatricsMQA benchmark and the increasing effectiveness of newer, more advanced multimodal models.

#### 4.4.1 PediatricsMQA(TQA)

**The effects of age on the performance** Table 11 illustrates the performance of various large language models on a pediatrics question answering dataset, with results broken down by different pediatric age groups: Prenate, Neonate, Infant, Toddler, Preschool, School-Age, and Adolescent. A consistent trend across all models is that performance varies between age groups, with no single age group being universally easier or harder for all models. Generally, the Llama-4-maverick (17b) and Gemini-2.0-flash models demonstrate the highest performance across most age categories, often achieving scores above 70%. Conversely, MedAlpaca (7b) and Llama-3.1 (8b) consistently show lower performance, typically below 45% across all age groups. For most models, there isn't a clear linear trend of increasing or decreasing performance with age; for instance, Llama-medx performs well in the Prenate and Adolescent groups but sees a dip in the Toddler category. Similarly, Gemini-1.5-flash shows relatively stable performance across most age groups with slight variations. The larger models, Llama-4-scout (17b) and Llama-4-maverick (17b), along with the Gemini series, generally outperform the smaller models like MedAlpaca (7b) and Llama-3.1 (8b), indicating a correlation between model size/sophistication and performance on this specialised medical question-answering task.

**Effects of topic category on TQA performance** Tables 4, 5, 6, 7, 8, 9, and 10 represent a list of 10 worst and best performing PediatricMQA(TQA) categories for Gemini-2.0-Flash, Gemini-1.0-Flash, MedAlpaca-7b, Llama-MedX, Llama-3.1 (8b), Llama-4-scout (17b) and Llama-4-maverick (17b) respectively. The results show that these models can score as low as 0% in some categories, while performing as high as 100% in other categories. In addition, models perform consistently badly at some categories, like "Lipid Disorders" and "Anorectal disorders", while being consistently good at other categories, such as "Developmental Psychology". This shows that there are some medical topics that various LLMs find consistently hard, requiring more training or better reasoning in these areas. These findings highlight both the potential and current limitations of LLMs in specialised pediatric medical reasoning, with implications for targeted dataset enrichment and model fine-tuning. The observed performance disparities across pediatric subdomains likely stem from variations in the complexity, specificity, and data representation of the topics within the models' training corpora. Categories such as Lipid Disorders, Pharmacology, and Neuroradiology, which consistently appear among the worst-performing, often involve dense biochemical knowledge, imaging interpretation, or nuanced pharmacokinetics—areas that require detailed, structured understanding and are less likely to be covered extensively or uniformly in publicly available medical text data. Conversely, high-performing categories like Developmental Psychology, Porphyria, and Paediatric Orthopaedic Disorders may benefit from more narrative-style content, clearer clinical patterns, or broader representation in educational materials and online resources. Furthermore, the consistent success in Developmental Psychology suggests that topics grounded in developmental milestones and behavioral patterns—often discussed in accessible formats—are more easily internalised by language models. These trends indicate that performance may be correlated not only with domain difficulty but also with the nature and quality of training data available for each category. Targeted augmentation with high-quality domain-specific data could help address these disparities and improve model reliability across underperforming clinical areas.

#### 4.4.2 PediatricsMQA(VQA)

**Effects of age on the performance** Table 12 presents the performance of various vision-language models on the PediatricsMQA (Visual Question Answering) dataset, disaggregated by pediatric age groups: Prenate, Neonate, Infant, Toddler, Preschool, School-Age, and Adolescent. Among the models evaluated, Huatuoqpt-vision (7B) consistently achieves the highest accuracy across most age groups, notably peaking at 73.77% in the Neonate and 73.48% in the Toddler categories. Gemini-2.0-flash also demonstrates relatively strong and stable performance, with scores ranging from 47.24% to 68.18%, outperforming its predecessor, Gemini-1.5-flash, across all age groups. In contrast, Llava-med-v1.5-mistral (7B) shows the lowest overall accuracy and more variable results, with its best performance (50.45%) in the Infant category and a marked decline in Preschool (26.76%). A general trend indicates that model performance tends to vary notably by age group, with the

Model	PediatricsMQA (TQA)	PediatricsQA [6]	PubMedQA [21]	MedQA [20]	MedMCQA [31]
MedAlpaca <sup>4</sup>	31.05	35.13	72.8	41.7	37.5
Llama-Medx <sup>5</sup>	50.43	55.18	73	61.04	60.53
Gemini-1.5-Flash[45, 34]	56.93	62.45	80.05	59.29	61.56
Gemini-2.0-Flash[45, 34]	70.61	74.54	90.1	79.0	70.77
LLama-3.1 (8B) [17]	38.53	42.96	55.20	44.87	43.24
Llama-4-scout (17B) [35]	66.14	67.74	70.03	74.69	68.80
Llama-4-Maverick (17B) [35]	<b>72.81</b>	<b>74.60</b>	<b>91.0</b>	<b>79.80</b>	<b>74.58</b>

Table 2: Results of TQA on various models for different datasets. Bold numbers represent the best-performing models in each dataset. The red cells represent the worst-performing dataset in each model.

Model	PediatricsMQA (VQA)	VQA-RAD [25]	SLAKE [27]	PathVQA [18]
LLaVa-Med (7B) [26]	34.95	51.4	48.6	56.8
HuatuogPT-Vision (7B) [11]	<b>56.70</b>	63.7	76.2	57.9
Gemini-1.5-Flash[45, 34]	30.01	64.94	73.80	66.27
Gemini-2.0-Flash[45, 34]	55.0	<b>68.33</b>	<b>80.79</b>	<b>75.26</b>

Table 3: Results of VQA on various models for different datasets. Bold numbers represent the best-performing models in each dataset. The red cells represent the worst-performing dataset in each model.

Neonate and Infant groups typically yielding higher accuracies, while performance tends to drop in the Adolescent and Preschool categories, highlighting the challenges models face in generalising across the developmental spectrum.

**Effects of anatomical region** The tables 17, 18, 19, and 20 present the best and worst performing anatomical regions in the PediatricsMQA(VQA) dataset across four different vision-language models: Gemini-2.0-flash, Gemini-1.5-flash, Huatuogpt-vision (7B), and Llava-med-v1.5-mistral (7B), respectively. Each table lists anatomical regions sorted by their question answering accuracy, with many regions consistently achieving perfect (100%) or zero (0) accuracy. A cross-model comparison reveals several persistent trends. Notably, regions associated with cardiovascular and lymphatic structures, such as the coronary artery, vertebral body, blood cells, and buccal mucosa cells—frequently appear among the best performing across all models. Conversely, anatomical sites such as the gums, genital regions, parietal and occipital regions, axilla, and bronchus consistently fall among the worst-performing. These patterns suggest that models are more proficient in recognising and reasoning over medically salient or frequently imaged internal structures, whereas more peripheral, less frequently annotated, or visually ambiguous areas tend to challenge model performance uniformly.

**Effects of modality of the performance** The tables 13, 14, 15, and 16 summarize the performance of various image modalities on the PediatricsMQA(VQA) dataset across four vision-language models: Gemini-2.0-flash, Gemini-1.5-flash, Huatuogpt-vision (7B), and Llava-med-v1.5-mistral (7B), respectively. Each table lists the ten best- and worst-performing modalities based on accuracy. A consistent trend across all models is the stark contrast in performance between modalities associated with visually rich, structured, or clinically interpretable data (e.g., optical, physical exam, surgical specimen, ihc staining)—which frequently achieve 100% accuracy—and those involving abstract, low-contrast, or complex image types (e.g., natural image, cytopathology, vce, sanger sequencing)—which often yield 0% accuracy. Additionally, modalities like radiograph, angiogram, and echocardiography appear among both the best and worst categories depending on the model, suggesting that model-specific strengths and weaknesses influence modality interpretation. This disparity highlights significant variability in how different vision-language architectures process and reason over medical imagery.

## 5 Limitations and future work

We believe that pediatricsVQA offers a formidable and challenging benchmark for medical applications in pediatrics. However, this work can be extended and enriched in various ways. In what follows, we list a few directions that we intend to follow:

- **Pediatrics leaderboard:** Although the LLM and VLM models used in this work are representative of the larger landscape of existing open and closed models, a more thorough evaluation of more models can be beneficial. We intend to create a leaderboard of LLMs on pediatrics, which will be updated with new models and more challenging pediatrics data.
- **Enriching the data:** Although PediatricsMQA has a comparable size to existing evaluation benchmarks, it can always be grown by adding more questions, topics, images, modalities and other dimensions of variability.
- **Adding more modalities:** In addition to text and images, we envision a more comprehensive and inclusive dataset containing videos and audio also. This can be significantly important for various conditions like autism.
- **Reasoning:** creating a more sophisticated set of QA pairs that require reasoning and multi-step thinking to be answered correctly.
- **Training:** The same processes used to build PediatricsMQA can be scaled to produce a larger dataset, which can be used to train a pediatrics specialist LLM/VLM.

## 6 Conclusion

This work introduces PediatricsMQA, a comprehensive benchmark designed to evaluate LLMs and VLMs in pediatric medical question answering. Addressing a critical gap in current medical AI research, PediatricsMQA captures the complexity and breadth of pediatric medicine across age groups, topics, anatomical regions, and imaging modalities. Extensive experiments show that pediatric content presents unique challenges, with consistently lower model performance compared to more general medical datasets. Model performance is influenced not only by scale and architecture but also by the nature of medical content—highlighting persistent weaknesses in underrepresented clinical domains and complex imaging types. These findings reaffirm the systemic neglect of pediatric-specific knowledge in existing AI systems and underscore the need for targeted dataset enrichment, pediatric-specific fine-tuning, and equitable evaluation strategies. PediatricsMQA serves as a step toward more inclusive, robust, and clinically reliable AI in healthcare.

### Broader Impact

PediatricsMQA represents a major advancement in addressing the systemic neglect of pediatric needs in medical AI. By offering a comprehensive, age-stratified benchmark across diverse topics and modalities, it tackles the age bias in current LLMs/VLMs, which are typically adult-focused—an important step given children’s historical underrepresentation in both medical research and AI training data.

- **Positive Societal Impacts:** PediatricsMQA can drive the creation of more equitable and reliable LLMs/VLMs for pediatric care, enabling AI tools that support clinical decisions, education, and patient communication across all age groups. By revealing model weaknesses across developmental stages, anatomy, and imaging types, it also advances safer AI deployment, with the potential to reduce diagnostic errors and improve outcomes in pediatric healthcare.
- **Negative Societal Impacts:** While this work offers valuable contributions, it also presents key risks. Increased focus on pediatric data heightens privacy concerns, especially if future dataset expansions lack strict ethical standards. There’s also a danger of over-reliance on LLMs/VLMs in sensitive clinical settings, where errors could cause real harm. Additionally, optimizing models for PediatricsMQA may lead to overfitting, limiting their effectiveness in real-world pediatric care.

In conclusion, while PediatricsMQA offers a critical tool for advancing fairness and capability in pediatric medical AI, it also necessitates responsible usage, continued human oversight, and proactive safeguards to mitigate ethical and societal risks.

## NeurIPS Paper Checklist

### 1. Claims

Question: Do the main claims made in the abstract and introduction accurately reflect the paper's contributions and scope?

Answer: [Yes]

Justification: The paper identifies a systemic pediatric underrepresentation problem in LLMs/VLMs and proposes PediatricsMQA as a new benchmark to evaluate and address this issue. Various LLM and VLM models are evaluated on PediatricsMQA and were shown to find this benchmark more challenging than other benchmarks of comparable sizes.

Guidelines:

- The answer NA means that the abstract and introduction do not include the claims made in the paper.
- The abstract and/or introduction should clearly state the claims made, including the contributions made in the paper and important assumptions and limitations. A No or NA answer to this question will not be perceived well by the reviewers.
- The claims made should match theoretical and experimental results, and reflect how much the results can be expected to generalize to other settings.
- It is fine to include aspirational goals as motivation as long as it is clear that these goals are not attained by the paper.

### 2. Limitations

Question: Does the paper discuss the limitations of the work performed by the authors?

Answer: [Yes]

Justification: Section 5 discusses different limitations that the paper has and potential future work to surpass them.

Guidelines:

- The answer NA means that the paper has no limitation while the answer No means that the paper has limitations, but those are not discussed in the paper.
- The authors are encouraged to create a separate "Limitations" section in their paper.
- The paper should point out any strong assumptions and how robust the results are to violations of these assumptions (e.g., independence assumptions, noiseless settings, model well-specification, asymptotic approximations only holding locally). The authors should reflect on how these assumptions might be violated in practice and what the implications would be.
- The authors should reflect on the scope of the claims made, e.g., if the approach was only tested on a few datasets or with a few runs. In general, empirical results often depend on implicit assumptions, which should be articulated.
- The authors should reflect on the factors that influence the performance of the approach. For example, a facial recognition algorithm may perform poorly when image resolution is low or images are taken in low lighting. Or a speech-to-text system might not be used reliably to provide closed captions for online lectures because it fails to handle technical jargon.
- The authors should discuss the computational efficiency of the proposed algorithms and how they scale with dataset size.
- If applicable, the authors should discuss possible limitations of their approach to address problems of privacy and fairness.
- While the authors might fear that complete honesty about limitations might be used by reviewers as grounds for rejection, a worse outcome might be that reviewers discover limitations that aren't acknowledged in the paper. The authors should use their best judgment and recognize that individual actions in favor of transparency play an important role in developing norms that preserve the integrity of the community. Reviewers will be specifically instructed to not penalize honesty concerning limitations.

### 3. Theory assumptions and proofs

Question: For each theoretical result, does the paper provide the full set of assumptions and a complete (and correct) proof?

Answer: [NA]

Justification: This paper proposes a benchmark. We focused on empirical studies rather than any theoretical exploration.

Guidelines:

- The answer NA means that the paper does not include theoretical results.
- All the theorems, formulas, and proofs in the paper should be numbered and cross-referenced.
- All assumptions should be clearly stated or referenced in the statement of any theorems.
- The proofs can either appear in the main paper or the supplemental material, but if they appear in the supplemental material, the authors are encouraged to provide a short proof sketch to provide intuition.
- Inversely, any informal proof provided in the core of the paper should be complemented by formal proofs provided in appendix or supplemental material.
- Theorems and Lemmas that the proof relies upon should be properly referenced.

#### 4. Experimental result reproducibility

Question: Does the paper fully disclose all the information needed to reproduce the main experimental results of the paper to the extent that it affects the main claims and/or conclusions of the paper (regardless of whether the code and data are provided or not)?

Answer: [Yes]

Justification: The data construction process is described in detail in section 3.1. In addition to giving the different prompts used to generate the data in section B. The models used for evaluation are also disclosed in section 4.2.

Guidelines:

- The answer NA means that the paper does not include experiments.
- If the paper includes experiments, a No answer to this question will not be perceived well by the reviewers: Making the paper reproducible is important, regardless of whether the code and data are provided or not.
- If the contribution is a dataset and/or model, the authors should describe the steps taken to make their results reproducible or verifiable.
- Depending on the contribution, reproducibility can be accomplished in various ways. For example, if the contribution is a novel architecture, describing the architecture fully might suffice, or if the contribution is a specific model and empirical evaluation, it may be necessary to either make it possible for others to replicate the model with the same dataset, or provide access to the model. In general, releasing code and data is often one good way to accomplish this, but reproducibility can also be provided via detailed instructions for how to replicate the results, access to a hosted model (e.g., in the case of a large language model), releasing of a model checkpoint, or other means that are appropriate to the research performed.
- While NeurIPS does not require releasing code, the conference does require all submissions to provide some reasonable avenue for reproducibility, which may depend on the nature of the contribution. For example
  - (a) If the contribution is primarily a new algorithm, the paper should make it clear how to reproduce that algorithm.
  - (b) If the contribution is primarily a new model architecture, the paper should describe the architecture clearly and fully.
  - (c) If the contribution is a new model (e.g., a large language model), then there should either be a way to access this model for reproducing the results or a way to reproduce the model (e.g., with an open-source dataset or instructions for how to construct the dataset).
  - (d) We recognize that reproducibility may be tricky in some cases, in which case authors are welcome to describe the particular way they provide for reproducibility. In the case of closed-source models, it may be that access to the model is limited in

some way (e.g., to registered users), but it should be possible for other researchers to have some path to reproducing or verifying the results.

#### 5. Open access to data and code

Question: Does the paper provide open access to the data and code, with sufficient instructions to faithfully reproduce the main experimental results, as described in supplemental material?

Answer: [Yes]

Justification: The code and data are made available following the code and data submission guidelines of the "datasets and benchmarks" track.

Guidelines:

- The answer NA means that paper does not include experiments requiring code.
- Please see the NeurIPS code and data submission guidelines (<https://nips.cc/public/guides/CodeSubmissionPolicy>) for more details.
- While we encourage the release of code and data, we understand that this might not be possible, so “No” is an acceptable answer. Papers cannot be rejected simply for not including code, unless this is central to the contribution (e.g., for a new open-source benchmark).
- The instructions should contain the exact command and environment needed to run to reproduce the results. See the NeurIPS code and data submission guidelines (<https://nips.cc/public/guides/CodeSubmissionPolicy>) for more details.
- The authors should provide instructions on data access and preparation, including how to access the raw data, preprocessed data, intermediate data, and generated data, etc.
- The authors should provide scripts to reproduce all experimental results for the new proposed method and baselines. If only a subset of experiments are reproducible, they should state which ones are omitted from the script and why.
- At submission time, to preserve anonymity, the authors should release anonymized versions (if applicable).
- Providing as much information as possible in supplemental material (appended to the paper) is recommended, but including URLs to data and code is permitted.

#### 6. Experimental setting/details

Question: Does the paper specify all the training and test details (e.g., data splits, hyper-parameters, how they were chosen, type of optimizer, etc.) necessary to understand the results?

Answer: [Yes]

Justification: we provide the experimental settings in section 4.3.

Guidelines:

- The answer NA means that the paper does not include experiments.
- The experimental setting should be presented in the core of the paper to a level of detail that is necessary to appreciate the results and make sense of them.
- The full details can be provided either with the code, in appendix, or as supplemental material.

#### 7. Experiment statistical significance

Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments?

Answer: [No]

Justification: We didn't report statistical significance results. However, due to the general consistency of LLMs we hypothesise that the results won't vary between runs, especially in flagship models like Gemini.

Guidelines:

- The answer NA means that the paper does not include experiments.

- The authors should answer "Yes" if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper.
- The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions).
- The method for calculating the error bars should be explained (closed form formula, call to a library function, bootstrap, etc.)
- The assumptions made should be given (e.g., Normally distributed errors).
- It should be clear whether the error bar is the standard deviation or the standard error of the mean.
- It is OK to report 1-sigma error bars, but one should state it. The authors should preferably report a 2-sigma error bar than state that they have a 96% CI, if the hypothesis of Normality of errors is not verified.
- For asymmetric distributions, the authors should be careful not to show in tables or figures symmetric error bars that would yield results that are out of range (e.g. negative error rates).
- If error bars are reported in tables or plots, The authors should explain in the text how they were calculated and reference the corresponding figures or tables in the text.

#### 8. Experiments compute resources

Question: For each experiment, does the paper provide sufficient information on the computer resources (type of compute workers, memory, time of execution) needed to reproduce the experiments?

Answer: [Yes]

Justification: Section 4.3 provides that information.

Guidelines:

- The answer NA means that the paper does not include experiments.
- The paper should indicate the type of compute workers CPU or GPU, internal cluster, or cloud provider, including relevant memory and storage.
- The paper should provide the amount of compute required for each of the individual experimental runs as well as estimate the total compute.
- The paper should disclose whether the full research project required more compute than the experiments reported in the paper (e.g., preliminary or failed experiments that didn't make it into the paper).

#### 9. Code of ethics

Question: Does the research conducted in the paper conform, in every respect, with the NeurIPS Code of Ethics <https://neurips.cc/public/EthicsGuidelines>?

Answer: [Yes]

Justification: We carefully observe the code of ethics during our work.

Guidelines:

- The answer NA means that the authors have not reviewed the NeurIPS Code of Ethics.
- If the authors answer No, they should explain the special circumstances that require a deviation from the Code of Ethics.
- The authors should make sure to preserve anonymity (e.g., if there is a special consideration due to laws or regulations in their jurisdiction).

#### 10. Broader impacts

Question: Does the paper discuss both potential positive societal impacts and negative societal impacts of the work performed?

Answer: [Yes]

Justification: Section 6 lists the broader positive and negative impacts of this work.

Guidelines:

- The answer NA means that there is no societal impact of the work performed.
- If the authors answer NA or No, they should explain why their work has no societal impact or why the paper does not address societal impact.
- Examples of negative societal impacts include potential malicious or unintended uses (e.g., disinformation, generating fake profiles, surveillance), fairness considerations (e.g., deployment of technologies that could make decisions that unfairly impact specific groups), privacy considerations, and security considerations.
- The conference expects that many papers will be foundational research and not tied to particular applications, let alone deployments. However, if there is a direct path to any negative applications, the authors should point it out. For example, it is legitimate to point out that an improvement in the quality of generative models could be used to generate deepfakes for disinformation. On the other hand, it is not needed to point out that a generic algorithm for optimizing neural networks could enable people to train models that generate Deepfakes faster.
- The authors should consider possible harms that could arise when the technology is being used as intended and functioning correctly, harms that could arise when the technology is being used as intended but gives incorrect results, and harms following from (intentional or unintentional) misuse of the technology.
- If there are negative societal impacts, the authors could also discuss possible mitigation strategies (e.g., gated release of models, providing defenses in addition to attacks, mechanisms for monitoring misuse, mechanisms to monitor how a system learns from feedback over time, improving the efficiency and accessibility of ML).

#### 11. Safeguards

Question: Does the paper describe safeguards that have been put in place for responsible release of data or models that have a high risk for misuse (e.g., pretrained language models, image generators, or scraped datasets)?

Answer: [No]

Justification: The dataset is scraped from previous public benchmarks and public open-access journals and sources. However, due to our reliance on LLMs to generate the data, we had to incorporate a manual curation process to remove any harmful or irrelevant questions and answers, which we described in section 3.1.

Guidelines:

- The answer NA means that the paper poses no such risks.
- Released models that have a high risk for misuse or dual-use should be released with necessary safeguards to allow for controlled use of the model, for example by requiring that users adhere to usage guidelines or restrictions to access the model or implementing safety filters.
- Datasets that have been scraped from the Internet could pose safety risks. The authors should describe how they avoided releasing unsafe images.
- We recognize that providing effective safeguards is challenging, and many papers do not require this, but we encourage authors to take this into account and make a best faith effort.

#### 12. Licenses for existing assets

Question: Are the creators or original owners of assets (e.g., code, data, models), used in the paper, properly credited and are the license and terms of use explicitly mentioned and properly respected?

Answer: [Yes]

Justification: all original creates are credited along the paper.

Guidelines:

- The answer NA means that the paper does not use existing assets.
- The authors should cite the original paper that produced the code package or dataset.
- The authors should state which version of the asset is used and, if possible, include a URL.

- The name of the license (e.g., CC-BY 4.0) should be included for each asset.
- For scraped data from a particular source (e.g., website), the copyright and terms of service of that source should be provided.
- If assets are released, the license, copyright information, and terms of use in the package should be provided. For popular datasets, [paperswithcode.com/datasets](https://paperswithcode.com/datasets) has curated licenses for some datasets. Their licensing guide can help determine the license of a dataset.
- For existing datasets that are re-packaged, both the original license and the license of the derived asset (if it has changed) should be provided.
- If this information is not available online, the authors are encouraged to reach out to the asset's creators.

### 13. **New assets**

Question: Are new assets introduced in the paper well documented and is the documentation provided alongside the assets?

Answer: [Yes]

Justification: The dataset and code are documented.

Guidelines:

- The answer NA means that the paper does not release new assets.
- Researchers should communicate the details of the dataset/code/model as part of their submissions via structured templates. This includes details about training, license, limitations, etc.
- The paper should discuss whether and how consent was obtained from people whose asset is used.
- At submission time, remember to anonymize your assets (if applicable). You can either create an anonymized URL or include an anonymized zip file.

### 14. **Crowdsourcing and research with human subjects**

Question: For crowdsourcing experiments and research with human subjects, does the paper include the full text of instructions given to participants and screenshots, if applicable, as well as details about compensation (if any)?

Answer: [NA]

Justification: Doesn't apply to us since we didn't have any human subjects or crowdsourced our process.

Guidelines:

- The answer NA means that the paper does not involve crowdsourcing nor research with human subjects.
- Including this information in the supplemental material is fine, but if the main contribution of the paper involves human subjects, then as much detail as possible should be included in the main paper.
- According to the NeurIPS Code of Ethics, workers involved in data collection, curation, or other labor should be paid at least the minimum wage in the country of the data collector.

### 15. **Institutional review board (IRB) approvals or equivalent for research with human subjects**

Question: Does the paper describe potential risks incurred by study participants, whether such risks were disclosed to the subjects, and whether Institutional Review Board (IRB) approvals (or an equivalent approval/review based on the requirements of your country or institution) were obtained?

Answer: [NA]

Justification: doesn't apply.

Guidelines:

- The answer NA means that the paper does not involve crowdsourcing nor research with human subjects.

- Depending on the country in which research is conducted, IRB approval (or equivalent) may be required for any human subjects research. If you obtained IRB approval, you should clearly state this in the paper.
- We recognize that the procedures for this may vary significantly between institutions and locations, and we expect authors to adhere to the NeurIPS Code of Ethics and the guidelines for their institution.
- For initial submissions, do not include any information that would break anonymity (if applicable), such as the institution conducting the review.

#### 16. **Declaration of LLM usage**

Question: Does the paper describe the usage of LLMs if it is an important, original, or non-standard component of the core methods in this research? Note that if the LLM is used only for writing, editing, or formatting purposes and does not impact the core methodology, scientific rigorousness, or originality of the research, declaration is not required.

Answer: [Yes]

Justification: We used LLMs in the data construction and evaluation process, which we described in section 3.1.

Guidelines:

- The answer NA means that the core method development in this research does not involve LLMs as any important, original, or non-standard components.
- Please refer to our LLM policy (<https://neurips.cc/Conferences/2025/LLM>) for what should or should not be described.

Figure 5: Examples of VQA pairs from the PediatricsMQA dataset.

## A Dataset

The dataset is available on HuggingFace<sup>6</sup>. Figures 4 and 5 give two examples of TQA and VQA pairs in the data.

## B Prompts and Templates

This section lists various prompts (Figures 6, 7, 8, 11, 12) and templates (9, 10) used during the construction and inference process. The captions of the images are self-descriptive.

<sup>6</sup><https://huggingface.co/datasets/adlbh/PediatricsMQA>

**TQA pairs Paraphrasing Prompt**

**### Instruction:**

- Paraphrase the following question and options without changing their meaning or the order of options.
- keep medical terms.
- Your output should have the following format:  
 { "question": "", "options": { "A": "", "B": "", "C": "", "D": "", "E": "" ... } }

**### Input:**  
 <ORIGINAL Question and Corresponding Options>

**### Response:**

Figure 6: Prompt for paraphrasing TQA pairs of PediatricsMQA.

**VQA Pairs Generation Prompt**

**### Instruction:**

- You are given an image and its corresponding title, caption and quotes.
- Generate 5 multiple-choice questions from the available information only, and provide your reasoning for each question.
- The questions need to be based on the caption, quotes.
- Only refer to the image in the questions, even if you use the caption or quote to create the question. Meaning your question should never contain any sentence similar or equivalent to "based on the caption".
- The questions should be as challenging as possible.
- Give your confidence (from 0 to 100) in each generated question's validity and corresponding answer.
- Your output should have the following JSON format:  
 [ { "confidence": "", "question": "", "options": { "A": "", "B": "", "C": "", "D": "" }, "answer": "A" or "B" or ..., "reasoning": "" }, ... ]

**Title:**  
 <IMAGE TITLE>

**Caption:**  
 <IMAGE CAPTION>

**Quotes:**  
 <IMAGE ARTICLE QUOTES>

**### Response:**

Figure 7: Prompt for Generating VQA pairs of PediatricsMQA based on scientific articles.

**FairVLMed VQA pairs generation prompt**

- From the image and the context generate 5 multiple choice questions.
- The questions should be visually answerable.
- The answer to the question should exist in the knowledge presented in the context, don't use any external knowledge.
- Non of the questions should be about the existence of glcoma in the image.
- Your output should have the following format:

```
[
{
"question": "",
"options": [
"A": "",
"B": "",
"C": "",
"D": ""
],
"answer": "A" or "B" or ...,
"reasoning": ""
},
...
]
```

## C Additional Results

### C.1 Text QA

#### C.1.1 Best and worst performance per topic category

Tables 4, 5, 6, 7, 8, 9, and 10 represent a list of 10 worst and best performing PediatricqMQA(TQA) categories for Gemini-2.0-Flash, Gemini-1.0-Flash, MedAlpaca-7b, Llama-MedX, Llama-3.1 (8b), Llama-4-scout (17b) and Llama-4-maverick (17b) respectively. The results show that these models can score as low as 0% in some categories, while performing as high as 100% in other categories. In addition, models perform consistently badly at some categories like "Lipid Disorders" and "Anorectal disorders", while being consistently good at other categories such as "Developmental Psychology". This shows that there are some medical topics that various LLMs find consistently hard, requiring more training or better reasoning in these areas. These findings highlight both the potential and current limitations of LLMs in specialised pediatric medical reasoning, with implications for targeted dataset enrichment and model fine-tuning. The observed performance disparities across pediatric subdomains likely stem from variations in the complexity, specificity, and data representation of the topics within the models' training corpora. Categories such as Lipid Disorders, Pharmacology, and Neuroradiology, which consistently appear among the worst-performing, often involve dense biochemical knowledge, imaging interpretation, or nuanced pharmacokinetics—areas that require detailed, structured understanding and are less likely to be covered extensively or uniformly in publicly available medical text data. Conversely, high-performing categories like Developmental Psychology, Porphyria, and Paediatric Orthopaedic Disorders may benefit from more narrative-style content, clearer clinical patterns, or broader representation in educational materials and online resources. Furthermore, the consistent success in Developmental Psychology suggests that topics grounded in developmental milestones and behavioral patterns—often discussed in accessible formats—are more easily internalised by language models. These trends indicate that performance may be correlated not

**Localization MCQs Template**

- Questions:
  - Where on the body is the pigmented lesion visible in this dermatoscopic view located?
  - Can you identify the anatomical site of the pigmented lesion in the provided dermatoscopic image?
  - On which part of the body is this pigmented lesion found, as seen in the dermatoscopic image?
  - What is the precise location on the skin where this pigmented lesion is situated (based on the dermatoscopic image)?
  - Referring to the dermatoscopic image, what is the body region exhibiting this pigmented lesion?
  - Could you specify the anatomical location of the pigmented lesion depicted in this dermatoscopic image?
  - Where on the patient's body is the pigmented lesion captured in this dermatoscopic view?
  - What is the regional anatomy of the pigmented lesion presented in this dermatoscopic image?
  - Based on the dermatoscopic image, which body surface area displays this pigmented lesion?
  - Can you pinpoint the exact body location of the pigmented lesion in this dermatoscopic image?
  - What is the dermatoscopic location of the pigmented lesion shown?
  - Identify the body site of the pigmented lesion as visualized under dermatoscopy.
  - Where is the pigmented skin lesion located according to the dermatoscopic image?
  - This dermatoscopic image shows a pigmented lesion on which part of the body?
  - What bodily region does the pigmented lesion in this dermatoscopic image occupy?
  - Can you describe the anatomical position of the pigmented lesion in the given dermatoscopic view?
  - Which area of the skin exhibits the pigmented lesion in the dermatoscopic image?
  - What is the topographical location of the pigmented lesion in this dermatoscopic image?
  - Where on the human anatomy is the pigmented lesion in the dermatoscopic image situated?
  - Please indicate the specific body surface location of the pigmented lesion as seen through the dermatoscope.
- Options:
  - Unknown
  - Scalp
  - Chest
  - Acral
  - Ear
  - Foot
  - Neck
  - Hand

### C.1.2 Performance by age group

Table 11 illustrates the performance of various large language models on a pediatrics question answering dataset, with results broken down by different pediatric age groups: Prenate, Neonate, Infant, Toddler, Preschool, School-Age, and Adolescent. A consistent trend across all models is that performance varies between age groups, with no single age group being universally easier or harder for all models. Generally, the Llama-4-maverick (17b) and Gemini-2.0-flash models demonstrate the highest performance across most age categories, often achieving scores above 70%. Conversely, MedAlpaca (7b) and Llama-3.1 (8b) consistently show lower performance, typically below 45% across all age groups. For most models, there isn't a clear linear trend of increasing or decreasing performance with age; for instance, Llama-medx performs well in the Prenate and Adolescent

groups but sees a dip in the Toddler category. Similarly, Gemini-1.5-flash shows relatively stable performance across most age groups with slight variations. The larger models, Llama-4-scout (17b) and Llama-4-maverick (17b), along with the Gemini series, generally outperform the smaller models like MedAlpaca (7b) and Llama-3.1 (8b), indicating a correlation between model size/sophistication and performance on this specialised medical question-answering task.

	Prenate	Neonate	Infant	Toddler	Preschool	School-Age	Adolescent

Table 11: The performance of different models for different age groups on the PediatricsMQA (TQA).

## C.2 Vision QA

### C.2.1 Performance by age group

Table 12 presents the performance of various vision-language models on the PediatricsMQA (Visual Question Answering) dataset, disaggregated by pediatric age groups: Prenate, Neonate, Infant, Toddler, Preschool, School-Age, and Adolescent. Among the models evaluated, Huatuoqpt-vision (7B) consistently achieves the highest accuracy across most age groups, notably peaking at 73.77% in the Neonate and 73.48% in the Toddler categories. Gemini-2.0-flash also demonstrates relatively strong and stable performance, with scores ranging from 47.24% to 68.18%, outperforming its predecessor, Gemini-1.5-flash, across all age groups. In contrast, Llava-med-v1.5-mistral (7B) shows the lowest overall accuracy and more variable results, with its best performance (50.45%) in the Infant category and a marked decline in Preschool (26.76%). A general trend indicates that model performance tends to vary notably by age group, with the Neonate and Infant groups typically yielding higher accuracies, while performance tends to drop in the Adolescent and Preschool categories, highlighting the challenges models face in generalizing across the developmental spectrum.

### C.2.2 Performance by modality

The tables 13, 14, 15, and 16 summarize the performance of various image modalities on the PediatricsMQA(VQA) dataset across four vision-language models: Gemini-2.0-flash, Gemini-1.5-flash, Huatuoqpt-vision (7B), and Llava-med-v1.5-mistral (7B), respectively. Each table lists the ten

	Prenate	Neonate	Infant	Toddler	Preschool	School-Age	Adolescent
Gemini-2.0-flash	56.55	68.18	61.25	57.83	54.02	58.44	47.24
Gemini-1.5-flash	23.81	40.00	31.43	16.67	34.69	33.33	32.89
Huatuogpt-vision (7B)	59.59	73.77	68.10	73.48	54.68	61.78	54.04
Llava-med-v1.5-mistral (7b)	29.94	32.35	50.45	42.40	26.76	35.87	35.28

Table 12: Results per age group on the PediatricsMQA(VQA) dataset for different models.

best- and worst-performing modalities based on accuracy. A consistent trend across all models is the stark contrast in performance between modalities associated with visually rich, structured, or clinically interpretable data (e.g., optical, physical exam, surgical specimen, ihc staining)—which frequently achieve 100% accuracy—and those involving abstract, low-contrast, or complex image types (e.g., natural image, cytopathology, vce, sanger sequencing)—which often yield 0% accuracy. Additionally, modalities like radiograph, angiogram, and echocardiography appear among both the best and worst categories depending on the model, suggesting that model-specific strengths and weaknesses influence modality interpretation. This disparity highlights significant variability in how different vision-language architectures process and reason over medical imagery.

Table 14: Ten best and worst performing modalities of PediatricsMQA(VQA) on Gemini-1.5-flash.

### C.2.3 Performance by anatomical regions

The tables 17, 18, 19, and 20 present the best and worst performing anatomical regions in the PediatricsMQA(VQA) dataset across four different vision-language models: Gemini-2.0-flash, Gemini-1.5-flash, Huatuogpt-vision (7B), and Llava-med-v1.5-mistral (7B), respectively. Each table lists anatomical regions sorted by their question answering accuracy, with many regions consistently achieving perfect (1.00) or zero (0.00) accuracy. A cross-model comparison reveals several persistent trends. Notably, regions associated with cardiovascular and lymphatic structures—such as the

Table 16: Ten best and worst performing modalities of PediatricsMQA(VQA) on Llava-med-v1.5-mistral (7b)

coronary artery, vertebral body, blood cells, and buccal mucosa cells—frequently appear among the best performing across all models. Conversely, anatomical sites such as the gums, genital regions, parietal and occipital regions, axilla, and bronchus consistently fall among the worst-performing. These patterns suggest that models are more proficient in recognising and reasoning over medically salient or frequently imaged internal structures, whereas more peripheral, less frequently annotated, or visually ambiguous areas tend to challenge model performance uniformly.
